(54) Title: BUYER, MULTI-SUPPLIER, MULTI-STAGE SUPPLY CHAIN MANAGEMENT SYSTEM

(57) Abstract: A global supply chain management system in an environment of multiple suppliers forming supply chains for one or more buyers using the Internet to enable rapid communication of supply information between the global supply chain management system and each buyer and each supplier. The system includes a global processor that maps "local" supply information for each buyer and each supplier, represented in one or more "local" property tables with one or more local tables for each buyer and each supplier, into "master" supply information, represented in one or more "master" supply tables common for multiple clients.

BUYER, MULTI-SUPPLIER, MULTI-STAGE SUPPLY CHAIN MANAGEMENT SYSTEM

5 BACKGROUND OF THE INVENTION

The present invention relates to internet commerce and particularly to methods and apparatus that enable efficient management of procurement transactions between buyers and suppliers in a supply chain that includes outsourcing with multiple suppliers.

10 Today, buyers and suppliers operate in a fast changing global environment where quantities needed, pricing, technical specifications and other supply parameters are frequently changing. The supply chain for procurement of goods and services requires economies of scale, market pricing and rapid delivery. The management of the process of procuring goods and services is known as “supply
15 chain management”.

Supply chain management is affected, for example, by the globalization of businesses, the proliferation of product and service variety, the increasing complexity of supply networks, and the shortening of product life cycles. Market conditions are susceptible to rapid demand fluctuation, inventory buildup, price
20 competition, and frequent specification changes. The supply chain for any particular company may be primarily internal supply. However, outsourcing is often used as an alternative to internal supply. By way of example, outsourcing is used to reduce costs, control inventories and respond to rapid demand changes. Outsourcing increasingly is involving more and more suppliers and supply chains
25 are growing more complex.

In fast changing markets, buyers require “current” and at times “real-time” quotes and other information from suppliers that specify, among other things, accurate quantities, prices and delivery times. The ability to rapidly exchange

information among buyers and suppliers is paramount to efficient supply chain management, particularly in an outsourcing environment.

5 The Internet is an efficient electronic link among buyers and suppliers for exchange of supply chain information. The Internet operates with open standards and permits easy, universal and secure information exchange. Many roles exist for the Internet in commerce and some of these roles have been described as “e-business”, “e-commerce”, and “internet commerce”. For purposes of the present specification, the term “internet commerce” (or “i-commerce”) is used to represent the role of the Internet in supply chain management.

10 “Internet commerce” enables companies, among other things, to realize greater efficiency, have better asset utilization, have faster times to market, reduce order fulfillment times, enhance customer services and penetrate new markets. The Internet provides an enormous capability for distribution of “current” information that is useful and necessary for improved supply chain management. “Current”
15 information often must be information available on a “real-time” or near “real time” basis. The Internet makes it possible to communicate “current” information about technology changes, availability of goods and services, up-to-date prices for goods and services and other information needed to manage a supply chain. When outsourcing is employed in the supply chain, the visibility into the current status
20 of the supply chain is more difficult and requires new and improved methods for insuring that complete, accurate and timely information is available. In the absence of such current information, the ability to react in a timely way to exceptions, abnormal events and other matters may be lost or delayed. When the time for taking action is not recognized or is delayed, supply chain management suffers and
25 ultimately the cost of goods and services increases.

 Although internet commerce simplifies many aspects of procurement, difficulties still exist and improvements are needed. One difficulty results because large numbers of suppliers and buyers are attached to the market place and each participant, whether buyer or supplier, tends to use different parameters,

terminology, terms, conditions and other information unique to the particular participant. These differences among participants result in an information exchange problem.

5 The information exchange problem is particularly acute, for example, in the outsourcing semiconductor manufacturing industry because goods and services procured from one supplier are frequently further processed by other suppliers in subsequent downstream stages. In order to have efficient and economical supply chain management, the interrelationship among each buyer and the upstream and down stream suppliers requires an exchange of "current" information that permits
10 real-time visibility into the status of the supply chain, fast identification of abnormal events and other information that permits exception management.

One difficulty that frustrates the good visibility necessary for supply chain management is the proliferation of different terminology and specifications used by each participant in the supply chain. While any dominating buyer (and
15 potentially any dominating supplier) can demand conformance with its way of doing business for its own business, the semiconductor manufacturing industry as a whole remains widely fragmented without much progress toward standardization. Furthermore, this fragmentation is increasing rather than decreasing so that problems are bound to exist for many years to come. The fragmentation exists, of
20 course, in many other industries.

Cooperative attempts have been made toward standardization in some industries. In the electronics component industry, the RosettaNet has the intent of providing industry wide standardization across the electronic components trading network. Some attempts have been made to standardize the semiconductor
25 manufacturing industry. Notwithstanding these attempts, the semiconductor manufacturing industry remains fragmented and neither the RosettaNet nor any other standard has become widely adopted.

Accordingly, there is a great demand for improved supply chain management methods and apparatus that will operate efficiently in fragmented markets.

5

SUMMARY

The present invention is a global supply chain management system in an environment of multiple suppliers forming supply chains for one or more buyers. The global supply chain management system includes a network connection, such as the Internet, for each buyer and each supplier to enable rapid communication of supply information between the global supply chain management system and each buyer and each supplier. The system includes a global processor with logic that maps "local" supply information for each buyer and each supplier, represented in one or more property tables having master information correlated to local information for each buyer and each supplier. This environment is fragmented, that is, the industry as a whole has not adopted any common set of standard terminology. In a fragmented industry, each instance of local supply information for any client (buyer or supplier) can be and usually is different from the local supply information for any other client (buyer or supplier). The embodiments of the present invention map supply information from and to the master internal property information to and from fragmented output local information according to the local property correlation for each buyer and each supplier. Notwithstanding the fragmentation among buyers and suppliers, the global supply chain management system functions to implement global supply chain management using "current" supply chain information supplied over the Internet using the fragmented local supply information used by the buyer or supplier.

20

25

To insure that the supply information is accurate, the global processor executes data integrity processes to improve the reliability of the supply information. The data integrity processes include data checking and data cleansing so that mapped supply information through error detection and correction becomes

more accurate than the original fragmented raw data. Data integrity processes are performed, for example, for data consistency within a record, data consistency within a report, data consistency across different reports from a particular supplier, data consistency between suppliers' and buyers' data and data consistency among suppliers.

Based upon a continuously updated data base having "current" supply information, the global processor provides reports for numerous data types including work-in-progress (WIP) reports, activity-based transaction reports (TR) that are created on a daily or other basis (including detail for each buyer and supplier stage), order reports, shipment reports and invoice reports. The terminology for the various reports and the items reported upon have no standard definitions. For example, *Orders* are known by different names including purchase orders (PO) that logically are for *goods* and work orders (WO) that logically are for *services*. However, common practice in many industries uses the term *Purchase Order* generically for any type of order whether for *goods* or *services*. These reports are all conveniently distributed over the Internet in a format and with the terminology selected by each client, whether the client is a buyer or a supplier.

With access to "current" supply information for multiple suppliers and with mapping capability among fragmented local property tables of multiple suppliers and buyers, the global processor enables the Internet placement of purchase orders and work orders (POs and WOs) that can be accompanied by detailed specifications using electronic attachments.

With access to "current" supply information for multiple suppliers and with mapping capability among fragmented local property tables of multiple suppliers and buyers, the global processor enables global planning from input to output of the supply chain. In the semiconductor manufacturing supply chain, the planning extends from Wafer (front end, upstream) planning to package/test (back end, down stream) planning.

The supply chain management system is able to provide lot tracking reports, actual cost lot detail reports, wafer rolling output reports, finished goods rolling output reports, work in progress inventory reports and other reports useful for supply chain management.

- 5 The supply chain management system employs planning based upon upstream visibility in the supply chain. Such capabilities are particularly useful in outsourcing to suppliers in a semiconductor supply chain. In the semiconductor IC-design outsourcing industry, the buyer (IC-design house) deals with multiple suppliers that provide various outsourcing functions at different supplier stages.
- 10 The buyer places a separate order (Purchase Order) with each supplier. Although the Purchase Orders are separate between a buyer and each supplier, each supplier depends on the previous supplier (upstream supplier) in the supply chain.

- In the semiconductor manufacturing industry in order to procure finished goods (for example a finished semiconductor chip), a buyer first orders wafers
- 15 from a Fab supplier (foundry); once the work at the Fab supplier is finished, the buyer orders sorting from a Wafer Sort supplier; after the Wafer Sort work is finished, the buyer orders Assembly from an Assembly supplier; and finally, the buyer orders Final Test from a Final Test supplier. The supply chain management system is able to perform group order generation for groups of dependent suppliers
- 20 (such as Fab, Wafer Sort, Assembly and Final Test suppliers) in the supply chain.

- The supply chain management system performs *alert* processes based upon alert conditions for specific events/reports/process of the supply chain. Alert reports are accessible to clients through i-commerce onscreen operations or through other methods of communication. Typically, alert conditions are
- 25 communicated daily (or more frequently if desired) in the form of event generation and alert messages.

 The input to the supply chain can take many forms and is a function of the particular industry. The input can be raw materials, groups of components or "lots"

of any kind. In the semiconductor manufacturing industry, frequently “lots” are “wafer lots” or “die lots”.

5 Lot Tracking is implemented by logic in the global processor to store detailed information related to a lot in the supply chain. The lot tracking information is categorized into two major parts, namely, static data where the data are fixed during the manufacturing processes and dynamic data where the data can be changed during the manufacturing processes. For example, the static data includes Date Code, Lot No, Order Date, Order Qty, Part No, Production Order No, PO No, Routing, Sup, and Unit Price. For example, the dynamic data includes two
10 main parts, namely, Date Information, {Completed Date, Hold Date, Received Date, Ship Date, Start Date} and Quantity Information (Completed Qty, Downgrade Qty, Goodpart Qty, Hold Qty, Received Qty, Returned Qty, Scrappart Qty, Ship Qty, Start Qty).

15 Lot tracking stores the genealogy of a lot in order to track and recall the lot history quickly. This tracking is done by storing the parent-child relationship for lots. For flexible in loading the lot tracking data, work-in-progress (WIP) reports and activity-based transaction reports (TR) are used.

20 Lot tracking is unique in the sense that a robust and consistent data set for the production and finance related information of a fragmented supply chain is maintained in one central place. The maintenance of such information permits performance checking, such as cycle time, yield analysis and cost reporting on a lot basis down to each stage of the supply chain.

25 The foregoing and other objects, features and advantages of the invention will be apparent from the following detailed description in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS
FIG. 1 depicts a plurality of supply chain management systems organized in part on an individual buyer basis and in an environment of multiple buyers and multiple suppliers forming a supply

chain and depicts a global supply chain management system for the multiple buyers and multiple suppliers.

FIG. 2 depicts further details of the global supply chain management system of FIG. 1 with a multi-stage, multi-lot processor for multiple buyers and multiple suppliers.

FIG. 3 depicts details of the supply chain management system of FIG. 1 and FIG. 2 with details for typical stages for processing.

FIG. 4 depicts details of a single one of the buyers and multiple suppliers for the multistage, multi-lot processing within the supply chain management system of FIG. 1 and FIG. 2.

FIG. 5 depicts one example of a purchase order set for a lot in the FIG. 4 system.

FIG. 6 depicts another example of a purchase order set for a lot in the FIG. 4 system.

FIG. 7 depicts another example of a purchase order set for a lot in the FIG. 4 system.

FIG. 8 depicts details of a multiple ones of the buyers and multiple suppliers for the multistage, multi-lot processing within the supply chain management system of FIG. 1.

FIG. 9 depicts a hardware block diagram of a computer system network for the supply chain management system of FIG. 1.

FIG. 10 depicts a software block diagram for the supply chain management system of FIG. 1.

FIG. 11 depicts a correlation processor for correlating input and output information among clients including mapping and data integrity processing in the FIG. 9 and FIG. 10 systems for supply chain management.

FIG. 12 depicts one example all of a multiple supplier branch in a supply chain transaction.

FIG. 13 depicts a cross supplier error checking in the example of FIG. 12.

FIG. 14 depicts one example of a lot tracking report.

FIG. 15 depicts a cross supplier lot tracking example 1.

FIG. 16 depicts a cross supplier lot tracking example 2.

FIG. 17 depicts an actual cost - lot detail report.

5 FIG. 18 depicts the purchase order logic flow for creation and acceptance of blanket purchase orders and purchase orders.

FIG. 19 depicts an example of Final Test purchase order.

FIG. 20 depicts an example of an attachment that appears as a thumbnail image in the Final Test purchase order of FIG. 19.

10 FIG. 21 depicts an example of a wafer rolling output report.

FIG. 22 depicts an example of a finished goods rolling output report with package planning.

FIG. 23 depicts an example of a work in progress inventory report.

15 DETAILED DESCRIPTION

FIG. 1 depicts a plurality of supply chain management systems 2-1, 2-2, ..., 2-M organized on an individual buyer (B) basis for the buyers 3-1, 3-2, ..., 3-B in an environment also including multiple suppliers 7-1, 7-2, ..., 7-S. FIG. 1 also depicts a supply chain management system 1 serving all the multiple buyers 3-1, 3-2, ..., 3-B and multiple suppliers 7-1, 7-2, ..., 7-S. The multiple buyers and multiple suppliers of FIG. 1 are connected over the internet and hence are able to exchange supply information rapidly and essentially in real time.

In FIG. 1, the local supply chain for each buyer includes supply stages 4 that typically include internal supply 5, that is, supply from the buyer's own organization, and outsourced supply 6, that is, supply from external suppliers 7-1, 7-2, ..., 7-S. Specifically, the buyers 3-1, 3-2, ..., 3-B have the supply stages 4-1, 4-2, ..., 4-B, each in turn having the internal supply 5-1, 5-2, ..., 5-SS and the external supply 6-1, 6-2, ..., 6-SS, respectively.

Each of the local supply chain management systems 2-1, 2-2, ..., 2-M are maintained, for example, by the individual buyers 3-1, 3-2, ..., 3-B and they are typically characterized as having their own terminology, specifications and other supply chain parameters. In FIG. 1, the suppliers and buyers as a whole are widely
 5 fragmented without much standardization. FIG. 1, therefore, as it encompasses local supply chain management systems 2-1, 2-2, ..., 2-M is representative of the semiconductor manufacturing industry.

Additionally, in FIG. 1, a global supply chain management system 1 is designed to overcome the local fragmentation and efficiently serve all the multiple
 10 buyers 3-1, 3-2, ..., 3-B and multiple suppliers 7-1, 7-2, ..., 7-S. The supply chain management system 1 includes a global processor 8 that uses network communications such as the Internet for overcoming the fragmentation of local supply chain management systems 2-1, 2-2, ..., 2-M and for providing integrated supply chain management. FIG. 2 depicts a supply chain management system
 15 operating in an environment of one or more buyers, B, including buyers B_0, B_1, \dots, B_B multiple suppliers, S, including suppliers S_0, S_1, \dots, S_S in a supply chain. The buyers and suppliers are connected to a Multi-stage, Multi-Lot Processor for Multiple Buyers (B) and Multiple Suppliers (S) where the supply chain includes inputs $I_0, I_1, \dots, I_i, \dots, I_I$ to the supply chain and outputs $O_0, O_1, \dots, O_o, \dots, O_O$ from
 20 the supply chain. The inputs are introduced to and the outputs are derived from Multiple Processing Stages (P) with Multiple Transactions (T) per Stage. The stages include $[P_{0,0}, P_{0,1}, \dots, P_{0,N}]; [P_{1,0}, \dots]; [\dots, P_{m,n}, \dots]; [P_{M,0}, \dots, P_{M,N}]$. Each stage such as a typical stage $P_{m,n}$ includes up to T transactions such as $T_0, T_1, \dots, T_i, \dots, T_T$.

FIG. 3 depicts details of the supply chain management system of FIG. 2 and details typical stages for processing. The one or more buyers, B, including $B_0, B_1, \dots, B_b, \dots, B_B$, and the multiple suppliers, S, including $S_0, S_1, \dots, S_s, \dots, S_S$ are in the supply chain. Stages $P_{m,n}$ and $P_{m,n+1}$ are typical of the many stages $[P_{0,0}, P_{0,1}, \dots, P_{0,N}]; [P_{1,0}, \dots]; [\dots, P_{m,n}, \dots]; [P_{M,0}, \dots, P_{M,N}]$ of FIG. 2. In particular, stage $P_{m,n}$

includes up to T transactions such as T_0, T_1, \dots, T_T . By way of example, stage $P_{m,n}$ includes transactions $(T_0), (T_1), (T_2), (T_3), (T_4), (T_5), \dots, (T_T)$ which are, for example, ORDER, WIP, YIELD, SHIPMENT, RECEIVE, WAREHOUSE, ..., PAYMENT. Many other transactions are possible, of course.

5 In FIG. 3, the stage $P_{m,n}$ is in the supply chain with B_b as the buyer and S_s as the supplier. By way of another example, the stage $P_{m,n+1}$ is also in the supply chain with B_b as the buyer and S_s as the supplier. The stage $P_{m,n+1}$ may include the transactions $(T_0), (T_1), (T_2), (T_3), (T_4), (T_5), \dots, (T_T)$ which are for $P_{m,n}$ ORDER, WIP, YIELD, SHIPMENT, RECEIVE, WAREHOUSE or stage $P_{m,n+1}$ may have a
10 different set of transactions.

FIG. 4 depicts details of a single one of the buyers and multiple suppliers for the multistage, multi-lot processing within the supply chain management system of FIG. 2. FIG. 4 depicts a supply chain management system operating in an environment of one buyer, B_b and multiple suppliers, S , including $S_0, S_1, S_2, S_3, S_4, S_5, \dots, S_s$ in a supply chain. The buyers and suppliers are connected to a
15 Multi-stage, Multi-Lot Processor for Multiple Buyers (B) and Multiple Suppliers (S) where the supply chain includes inputs $I_0, I_1, I_2, \dots, I_l$ to the supply chain and outputs $O_0, O_1, O_2, \dots, O_o$ from the supply chain. The inputs are introduced to and the outputs are derived from Multiple Processing Stages (P) with Multiple
20 Transactions (T) per Stage. The stages include $[P_{0,0}, P_{0,1}, P_{0,2}, P_{0,3}], [P_{1,0}, P_{1,1}, P_{1,2}, P_{1,3}], \dots, [P_{x,0}, P_{x,1}, P_{x,2}, P_{x,3}], \dots, [P_{M,0}, \dots, P_{M,3}]$. Each of those stages includes a set of up to T transactions such as $T_0, T_1, \dots, T_b, \dots, T_T$ like those described in connection with FIG. 2.

In FIG. 4, buyer, B_b initiates operation of the supply chain in connection
25 with a purchase by authorizing inputs I_1 and I_2 . The I_1 input, such as a semiconductor lot (wafer lot or die lot), to the supply chain progresses through a first sequence of stages $[P_{0,0}, P_{x,1}, P_{1,2}, P_{1,3}]$ to the output O_1 . The supplier for the stage $P_{0,0}$ stage is S_0 , the supplier for the stage $P_{x,1}$ stage is S_2 , the supplier for the stage $P_{1,2}$ stage is S_3 and the supplier for the stages $P_{1,3}$ stage is S_5 . Similarly, the I_2

input, such as a semiconductor lot, to the supply chain progresses through a second sequence of stages $[P_{0,0}, P_{0,1}, P_{x,2}, P_{x,3}]$ to the output O_2 . The supplier for the stage $P_{0,0}$ stage is S_0 , the supplier for the stage $P_{0,1}$ stage is S_1 , the supplier for the stage $P_{x,2}$ stage is S_4 and the supplier for the stages $P_{x,3}$ stage is S_5 . FIG. 4 depicts details of a single one of the buyers and multiple suppliers for the multistage, multi-lot processing within the supply chain management system of FIG. 1.

FIG. 5 depicts one example of a purchase order set for multistage processing in the FIG. 4 system. In FIG. 5, buyer, B_b , initiates operation of the supply chain in connection with a purchase by authorizing input I_1 . The input I_1 to the supply chain progresses through a sequence of stages $[P_{0,0}, P_{x,1}, P_{1,2}, P_{1,3}]$ to provide the output O_1 . The supplier for the stage $P_{0,0}$ stage is S_0 , the supplier for the stage $P_{x,1}$ stage is S_2 , the supplier for the stage $P_{1,2}$ stage is S_3 and the supplier for the stages $P_{1,3}$ stage is S_5 . In order for the work to be performed through the stages $[P_{0,0}, P_{x,1}, P_{1,2}, P_{1,3}]$ of FIG. 5, orders authorizing and specifying the terms and conditions associated with the work are agreed upon by the buyer, B_b , and the suppliers S_0 , S_2 , S_3 , and S_5 . The orders in FIG. 5 are designated $P_{0,0}S_0$, $P_{x,1}S_2$, $P_{1,2}S_3$ and $P_{1,3}S_5$. These orders are called "purchase orders" or "work orders" and apply to goods and services. In some industries, both goods and services are involved but in other industries either goods or services alone are involved.

In a semiconductor manufacturing environment, both goods and services are involved. Typically, the I_1 input is a lot (wafer lot or die lot) and the processing stages are typically Fab, Wafer Sort, Assembly and Final Test. Other stages are of course possible and include, for example, Packaging (such as tape and reel), Bumping and Marking. The processing stages Fab, Wafer Sort, Assembly and Final Test are each performed by a supplier and typically the different suppliers S_0 , S_2 , S_3 , and S_5 . The work at each of the processing stages of Fab, Wafer Sort, Assembly and Final Test is authorized and controlled by the purchase orders $P_{0,0}S_0$, $P_{x,1}S_2$, $P_{1,2}S_3$ and $P_{1,3}S_5$, respectively. The output from the stages $[P_{0,0}, P_{x,1}, P_{1,2}, P_{1,3}]$ are represented by $[G_{0,0}, G_{x,1}, G_{1,2}, O_1]$, respectively. In FIG. 5, the set of purchase

orders $[P_{0,0}S_0, P_{x,1}S_2, P_{1,2}S_3, P_{1,3}S_5]$ relate to interdependent work steps. The output, O_1 , is only obtained when all of the orders $[P_{0,0}S_0, P_{x,1}S_2, P_{1,2}S_3, P_{1,3}S_5]$ have been executed according to their terms and in sequence from the most upstream order $P_{0,0}S_0$ in turn through the orders $P_{x,1}S_2, P_{1,2}S_3$ to the most downstream order $P_{1,3}S_5$.

5 Furthermore, the downstream orders depend upon the performance of the upstream orders. Typically, in the semiconductor manufacturing industry, the output at any stage is a variable, for example, varying as to supply chain parameters such as quantity, quality and delivery time. Accordingly, orders with downstream suppliers often need to be conditioned upon the results of one or more upstream suppliers.

10 When information in a supply chain is not accurate and “current”, the entire supply chain can become inefficient, subject to distortion and unstable. One of the common distortion problems is escalating over-requirement forecasts that tend to greatly exceed market demand. Such escalation is sometimes referred to as a “bullwhip” effect. The “bullwhip” results when each supplier in the supply chain
15 over states actual demand. The over demand escalates as forecasts are propagated downstream in the supply chain. Each downstream supplier amplifies the over-requirement of the previous stage.

In the FIG. 5 purchase order set, each of the suppliers receives “current” and accurate information from upstream suppliers through use of communications
20 over the Internet. The “current” information helps to reduce supply chain escalation of over requirements.

FIG. 6 depicts another example of a purchase order set for multistage processing in the FIG. 4 system. In FIG. 6, buyer, B_b , initiates operation of the supply chain in connection with a purchase by authorizing input I_2 . The input I_2 to
25 the supply chain progresses through a sequence of stages $[P_{0,0}, P_{0,1}, P_{x,2}, P_{x,3}]$ to provide the output O_2 . The supplier for the stage $P_{0,0}$ stage is S_0 , the supplier for the stage $P_{0,1}$ stage is S_1 , the supplier for the stage $P_{x,2}$ stage is S_4 and the supplier for the stages $P_{x,3}$ stage is S_5 . In order for the work to be performed through the stages $[P_{0,0}, P_{0,1}, P_{x,2}, P_{x,3}]$ of FIG. 6, orders authorizing and specifying the terms and

conditions associated with the work are agreed upon by the buyer, B_b , and the suppliers S_0 , S_1 , S_4 , and S_5 . The orders in FIG. 6 are designated $P_{0,0}S_0$, $P_{x,1}S_2$, $P_{1,2}S_3$ and $P_{1,3}S_5$.

5 In a semiconductor manufacturing environment, the I_2 input is a wafer lot and the processing stages are typically Fab, Wafer Sort, Assembly and Final Test each performed by a supplier and typically the different suppliers S_0 , S_1 , S_4 , and S_5 , respectively. The work at each of the processing stages of Fab, Wafer Sort, Assembly and Final Test is authorized and controlled by the orders $P_{0,0}S_0$, $P_{0,1}S_1$, $P_{x,2}S_4$ and $P_{x,3}S_5$, respectively. The output from the stages [$P_{0,0}$, $P_{0,1}$, $P_{x,2}$, $P_{x,3}$] are
 10 represented by [$G_{0,0}$, $G_{0,1}$, $G_{x,2}$, O_2], respectively. In FIG. 6, the set of purchase orders [$P_{0,0}S_0$, $P_{0,1}S_1$, $P_{x,2}S_4$, $P_{x,3}S_5$] relate to interdependent work steps. The output, O_2 , is only obtained when all of the orders [$P_{0,0}S_0$, $P_{0,1}S_1$, $P_{x,2}S_4$, $P_{x,3}S_5$] have been executed according to their terms and in the sequence from the most upstream order $P_{0,0}S_0$ in turn through the orders $P_{0,1}S_1$, $P_{x,2}S_4$ to the most downstream order
 15 $P_{x,3}S_5$.

In the FIG. 6 purchase order set, each of the suppliers receives “current” and accurate information from upstream suppliers through use of communications over the Internet. The “current” information helps to reduce supply chain escalation of over requirements.

20 FIG. 7 depicts another example of a purchase order set for multistage processing in the FIG. 4 system. In FIG. 7, buyer, B_b , initiates operation of the supply chain in connection with a purchase by authorizing input I_3 . The input I_3 to the supply chain progresses through a sequence of stages commencing with a stage $P_{0,0}$ and thereafter split into two sequences, namely, [$P_{x,1}$, $P_{1,2}$, $P_{1,3}$] to provide the
 25 output O_3 and [$P_{x+1,1}$, $P_{0,2}$, $P_{0,3}$] to provide the output O_4 . The supplier for the stage $P_{0,0}$ stage is S_0 , the supplier for the stage $P_{x,1}$ stage is S_2 , the supplier for the stage $P_{1,2}$ stage is S_3 and the supplier for the stages $P_{1,3}$ stage is S_5 and the supplier for the stage $P_{x+1,1}$ stage is S_6 , the supplier for the stage $P_{0,2}$ stage is S_7 and the supplier for the stages $P_{0,3}$ stage is S_8 . In order for the work to be performed through the stage

$P_{0,0}$ an order authorizing and specifying the terms and conditions associated with the work are agreed upon by the buyer, B_b , and the supplier S_0 . In order for the work to be performed through the stages $[P_{x,1}, P_{1,2}, P_{1,3}]$ of FIG. 7, orders authorizing and specifying the terms and conditions associated with the work are agreed upon by the buyer, B_b , and the suppliers S_2 , S_3 and S_5 . In order for the work to be performed through the stages $[P_{x+1,1}, P_{0,2}, P_{0,3}]$ of FIG. 7, orders authorizing and specifying the terms and conditions associated with the work are agreed upon by the buyer, B_b , and the suppliers S_6 , S_7 and S_8 . The orders in FIG. 7 are designated $[PO_{0,0}S_0]$, $[PO_{x,1}S_2, PO_{1,2}S_3, PO_{1,3}S_5]$ and $[PO_{x+1,1}S_6, PO_{0,2}S_7, PO_{0,3}S_8]$.

In a semiconductor manufacturing environment, the I_3 input is a wafer lot and the processing stages are typically Fab, Wafer Sort, Assembly and Final Test each performed by a supplier and typically the different suppliers $[S_0]$, $[S_2$ and $S_6]$, $[S_3$ and $S_7]$ and $[S_5$ and $S_8]$, respectively. The work at each of the processing stages of Fab, Wafer Sort, Assembly and Final Test is authorized and controlled by the orders $[PO_{0,0}S_0]$, $[PO_{x,1}S_2, PO_{1,2}S_3, PO_{1,3}S_5]$ and $[PO_{x+1,1}S_6, PO_{0,2}S_7, PO_{0,3}S_8]$. The output from the stage $P_{0,0}$ is split and is represented by $[{}_1G_{0,0}$ and ${}_2G_{0,0}]$. The outputs from the stages $[P_{x,1}, P_{1,2}, P_{1,3}]$ are represented by $[G_{x,1}, G_{1,2}, O_3]$, respectively. The outputs from the stages $[P_{x+1,1}, P_{0,2}, P_{0,3}]$ are represented by $[G_{x+1,1}, G_{0,2}, O_4]$, respectively.

In FIG. 7, the sets of purchase orders $[PO_{0,0}S_0]$, $[PO_{x,1}S_2, PO_{1,2}S_3, PO_{1,3}S_5]$ and $[PO_{x+1,1}S_6, PO_{0,2}S_7, PO_{0,3}S_8]$ relate to interdependent work steps. The output, O_3 , is only obtained when all of the orders $[PO_{0,0}S_0]$ and $[PO_{x,1}S_2, PO_{1,2}S_3, PO_{1,3}S_5]$ have been executed according to their terms and in the sequence from the most upstream order to the most downstream order. The output, O_4 , is only obtained when all of the orders $[PO_{0,0}S_0]$ and $[PO_{x+1,1}S_6, PO_{0,2}S_7, PO_{0,3}S_8]$ have been executed according to their terms and in the sequence from the most upstream order to the most downstream order. Further each of the subset order sequences $[PO_{x,1}S_2, PO_{1,2}S_3, PO_{1,3}S_5]$ and $[PO_{x+1,1}S_6, PO_{0,2}S_7, PO_{0,3}S_8]$ are interdependent in that they both drive from the parent order $[PO_{0,0}S_0]$.

In the FIG. 7 purchase order set, each of the suppliers receives "current" and accurate information from upstream suppliers through use of communications over the Internet. The "current" information helps to reduce supply chain escalation of over requirements. The FIG. 7 sequences indicate the complexity that arises among suppliers in a multistage supply chain typical of outsourcing in the semiconductor manufacturing industry when only a single buyer, B_b is considered.

FIG. 8 depicts a supply chain management system 1 operating in an environment of multiple buyers (B) 3 including buyers ($B_0, B_1, \dots, B_b, \dots, B_B$) 3-1, 3-2, ...3-b, ..., 3-B and multiple suppliers (S) 7 including suppliers (S_0, S_1, \dots, S_S) 7-1, 7-2, ..., 7S in a supply chain. The buyers 3 and suppliers 7 are connected to a multi-stage, multi-lot processor 8' that is one embodiment of the global processor 8 of FIG. 1. In FIG. 8, the buyer B_b is typical of all the buyers $B_0, B_1, \dots, B_b, \dots, B_B$ and buyer B_b places orders and receives goods and services from a multistage supply chain $P\{B_b\}$ 4-b. The multistage supply chain $P\{B_b\}$ is like any of the multistage supply chains described in connection with FIG. 1 through FIG. 7. For the semiconductor manufacturing industry, the multistage supply chain $P\{B_b\}$ includes a plurality of stages P_{bx} organized functionally, for example, into Fab, Wafer Sort, Assembly and Final Test stages. The stages P_{bx} are like any of the stages described in connection with FIG. 1 through FIG. 7. The single buyer B_b is typical and more generally all the buyers $B_0, B_1, \dots, B_b, \dots, B_B$ are associated with multistage supply chains $P\{B_0\}, P\{B_1\}, \dots, P\{B_b\}, \dots, P\{B_B\}$, respectively. The stages P_{bx} for any particular one of the supply chains $P\{B_0\}, P\{B_1\}, \dots, P\{B_b\}, \dots, P\{B_B\}$ may be same as or different from the stages P_{bx} for any other ones of the supply chains $P\{B_0\}, P\{B_1\}, \dots, P\{B_b\}, \dots, P\{B_B\}$. FIG. 8 indicates the great complexity of the supply chain environment for multiple buyers and multiple suppliers common in many industries such as the semiconductor manufacturing industry.

FIG. 9 depicts a hardware block diagram of a computer system network for the supply chain management system of FIG. 1. In FIG. 9, the

CLIENT(BUYER/SUPPLIER) 91-1, the CLIENT(BUYER/SUPPLIER) 91-2 and the CLIENT(BUYER/SUPPLIER) 91-C connect over INTERNET 99 to MULTI-STAGE, MULTI-LOT PROCESSOR 8 and particularly to the SWITCH 92. The SWITCH 92 functions to switch incoming and outgoing traffic between the

5 LOAD BALANCER 93-1 and the LOAD BALANCER 93-2. The LOAD BALANCER 93-1 and the LOAD BALANCER 93-2 connect between the SWITCH 94-1 and the SWITCH 94-2. The SWITCH 94-1 and the SWITCH 94-2 connect to the APPLICATION SERVER 95-1 and the APPLICATION SERVER 95-2. The APPLICATION SERVER 95-1 and the APPLICATION SERVER 95-2 execute

10 programs for performing supply chain management in the multiple buyer, multiple supplier environment. The APPLICATION SERVER 95-1 and the APPLICATION SERVER 95-2 connect through DATA SERVER 96-1 and DATA SERVER 96-2 to the DISK ARRAY 97 which includes the disks MAIL 97-1, DATABASE 97-2 and LOG-IN 97-3. The processor 8 of FIG. 9 includes two-way redundancy for

15 providing highly reliable and highly available supply chain management services to the buyers and suppliers that are the clients in the network.

FIG. 10 depicts a software block diagram for the supply chain management system of FIG. 1. In FIG. 9, the CLIENT (BUYER/SUPPLIER) 91-1, the CLIENT (BUYER/SUPPLIER) 91-2 and the CLIENT (BUYER/SUPPLIER) 91-C connect

20 over INTERNET 99 to MULTI-STAGE, MULTI-LOT PROCESSOR 8 and particularly to the SECURITY/SWITCH 92'. The SECURITY/SWITCH 92' functions to perform security checks on the internet traffic and to switch incoming and outgoing traffic between the WEB 98-1 and the BUSINESS LOGIC 98-2 executing in the PROCESS SERVERS 95'. The WEB 98-1 and the BUSINESS

25 LOGIC 98-2 and the APPLICATION SERVER 95-2 connect to the DATA SERVER 97' which includes MAIL 97'-1, DATABASE 97'-2 and LOG-IN 97-3 functions. The WEB 98-1 process functions are primarily for real-time interactive communications between the DATA SERVER 97' and CLIENTs 91-1, 91-2, ..., 91-C. The BUSINESS LOGIC 98-2 is primarily for performing the operations

necessary for supply chain management services in the multiple buyer, multiple supplier environment. The BUSINESS LOGIC 98-2 is logic means for accessing master information for executing supply chain management functions for the clients to provide management data.

5 FIG. 11 depicts a CORRELATION PROCESSOR 98'-2 for correlating input and output information among clients. The correlation is among the local and fragmented information that is different for each client. In the particular embodiment of FIG. 11, the CORRELATION PROCESSOR 98'-2 performs mapping and data integrity processing in connection with the supply chain management. In FIG. 11, the CLIENTs 91-1, 91-2, ..., 91-C connect over
10 INTERNET 99 to the CORRELATION PROCESSOR 98'-2. The CORRELATION PROCESSOR 98'-2 is part of the BUSINESS LOGIC 98-2 of FIG. 10. The MESSAGE FILE CONNECTOR 88-1 functions using conventional internet protocols (httpRobot, ftpRobot, ftpServer) for incoming and outgoing
15 communications over the INTERNET 99. The FILE MONITOR 88-2 detects the file format and makes conventional conversion to comma separated values (for example, flat2csv, xls2csv). The CONVERTER 88-3 converts the csv values to an xml format as an input to the INPUT MAPPER 88-4. The INPUT MAPPER 88-4 functions to map the local property values inherent in the input data to master
20 property values defined by the supply chain management system. The INPUT MAPPER 88-4 accesses the PROPERTY TABLES in the DATABASE 97'-2 to do the mapping. After mapping, the mapped raw input data is converted in CONVERTER 88-5 from an xml format to a database format (xml TO db) and stored in the RAW DATA store 88-7₁. The mapped raw input data is then
25 processed in the DATA INTEGRITY UNIT 88-6 including the Data Checking unit 88-6₁ and the Data Cleansing 88-6₂. The checked and cleaned processed input data is stored The checked and cleaned raw data is processed in the PROCESS DATA UNIT 98 and the processed data is stored in the PROCESSED DATA store 88-7₂. Any of the raw data in the RAW DATA store 88-7₁ or the processed data in the

PROCESSED DATA store 88-7₂ can be communicated to the CLIENTs 91-1, 91-2 and 91-C using the OUTPUT MAPPER 88-8 to map the output data to the form expected by the client. The OUTPUT MAPPER 88-8 functions to map the master property information defined by the supply chain management system to the local
 5 property information of the type and form used by clients as revealed in the input data from clients. The OUTPUT MAPPER 88-8 is an output mapping means for mapping management data to local data for clients. The OUTPUT MAPPER 88-8 accesses the PROPERTY TABLES in the DATABASE 97'-2 to do the mapping.

Different buyers, such as Fabless semiconductor companies, frequently
 10 require different information from their suppliers' daily or other reports. Often suppliers can provide only one format for these reports to all of their buyers due to the constraints in their computer systems. To bridge this information gap, the supply chain management system uses a database schema which provides a master property table holding a super set of information for all the clients (buyers and
 15 suppliers) using the system. When the buyers and suppliers send their records, reports and inquiries to the supply chain management system, the data are mapped into the master database schema.

A client-specific property file is created to describe the client-specific ("local") data for each client. In one embodiment, MicroSoft BizTalk is used to
 20 generate a schema.biz and mapper.biz to define the mapping between a client's local data and the master database schema. Then, a JAVA class, CSV2XML, is applied to convert these data reports from .DBF, .XLS or .CSV format into XML format files based on the description in the corresponding local property files. The XML style sheet file, .XSL, generated by the mapper.biz and the JAVA class,
 25 XML2DB, are used to convert the report data into the final format to be imported into the master table of the database.

The master table can be in any form including indexed files, linked sub-tables, linked lists, among others. The following TABLE 1 is an example of a master property table where the column "Field Name" represents the master table

name and the column "Description" briefly describes the general use of the Field Name. TABLE 1 is representative of a master table and is not intended to be exhaustive. Other fields are added as the need arises.

TABLE 1 Copyright 2002 GetSilicon, Inc.		
	Field Name	Description
1	Actual Charge	Charge for Units actually delivered as Final Product
2	Actual Qty	Quantity of Units actually delivered as Final Product
3	Back Issue Die Qty	Back Issued Die Qty
4	Base Lot	Derived Base Lot number from the lot genealogy specification
5	Bin	Physical bin location
6	Completed Date	Date on which the manufacturing process completes
7	Completed Die Qty	Number of dies completed in the processing
8	Completed Qty	Number of Units completed in the processing
9	Completed Wafer Qty	Number of wafers completed in the processing
10	Date Code	Code to designate the manufacturing date of product
11	Description	Description of process parameters
12	Device Type	Type of device
13	Down Grade Qty	Number of Units being downgraded to lower specs after production
14	Est Amount	Estimated finished goods amount
15	Est_FG_Date	Estimated finished goods date
16	Est_FG_Qty	Estimated finished goods quantity
17	Estimate Complete Date	Revised completion date based on the current process information
18	ETA Date	Date of estimated time of arrival
19	Good Unit Qty	Number of good Units
20	Gross Ship Weight	Gross weight as shipped
21	Hold Date	Date Hold starts
22	Hold Qty	Number of Units on hold
23	I_No	Identification number for product
24	Invoice Date	Invoice created date
25	Invoice No	Invoice number
26	Lot No	Number for Client derived from Base Lot number
27	Net Shipping Weight	Net weight as shipped

TABLE 1
Copyright 2002 GetSilicon, Inc.

	Field Name	Description
	28 Notes	Special instructions and details
	29 Order Confirm Date	Date order confirmed
	30 Order Date	Date on which the production order is issued
5	31 Order Qty	Quantity ordered
	32 Order Req Date	Date order requested
	33 Ordered Die Qty	Ordered die qty
	34 Ordered Wafer Qty	Ordered wafer qty
	35 Part No	Part number
	36 PO No	Purchase Order number
10	37 PO Rev No	Revolution of PO No
	38 Process	Name of detailed process used by Supplier
	39 Production Order No	Number for production order
	40 Received Date	Date on which Units are received
	41 Received Die Qty	Number of die received for the manufacturing process

	57 Shipping Notice No	Number on shipping package

TABLE 1 Copyright 2002 GetSilicon, Inc.		
	Field Name	Description
58	Start Date	Date on which the processing begins
59	Start Qty	Number of Units when the processing starts
60	Sup	Supplier name
61	Topmark	Topmark visible on top of finished goods
5	62 Unit	Unit type such as Wafer, Die
	63 Unit Price	Unit price per Unit
	64 Weighted Completed Date	Weighted completed date, based on the quantity
	65 Weighted Received Date	Weighted received date, based on the quantity
	66 Weighted Ship Date	Weighted ship date, based on the quantity
10	67 Weighted Start Date	Weighted start date, based on the quantity
	68 WIP Die Qty	Number of dies that is active in the production process
	69 WIP Wafer Qty	Number of wafers that is active in the production process
	70 WO No	Work Order No
	71 WO Rev No	Work Order Rev
15	72 Yield	Output over input (in percent)

The following TABLE 2, TABLE 3 and TABLE 4 are examples of the master property table and the corresponding local client information mapping. In TABLE 2, the column "Field Name" represents the master table information, the column "Buyer1" represents a buyer client local client information of a buyer and the columns "Fab1", "Wafer Sort1", "Assembly1" and "Test1" represent local client information of four suppliers representing different stages of semiconductor manufacturing.

In TABLE 3, the column "Field Name" represents the master table information, the column "Buyer1" represents local client information of a buyer and the columns "Wafer Sort1" and "Wafer Sort2" represent local client information of two suppliers representing the same Wafer Sort stage of semiconductor manufacturing.

In TABLE 4, the column "Field Name" represents the master table information, the column "Buyer1" represents a buyer client local client information of a buyer and the columns "Assembly1", "Assembly2" and "Assembly3" represent local client information of two suppliers representing the same Assembly stage of semiconductor manufacturing. Certain ones of the fields in TABLE 1 derive directly from client fields while others are derived as a result of processing.

Examples of derived fields include:

1) *Base Lot*. A derived number used for tracking the lot geneology for a buyer through all suppliers.

2) *In-Date*. A derived date that is the earliest date associated with any transaction at a client, for example, the earlier of the *Received Date* and the *Start Date*.

3) *Out-Date*. The latest date associated with any transaction at a client, for example, the later of the *Complete Date* and the *Ship Date*.

4) The term *Qty* generally means quantities that have been accumulated to show totals for one or more transactions or parts of a transaction.

5) The term *Weighted* refers to dates weighted by quantity. For example, for 100 pcs received on 6/5/2002 0:0:0 and 200 pcs received on 6/6/2002 0:0:0, the *Weighted Received Date* is: $(date1 * qty1 + date2 * qty2) / (qty1 + qty2)$, the *Weighted Received Date* is: 6/5/2002 18:0:0.

6) *Est_FG_Date*. The estimated finished good date, the date which the current material will be available as finished goods. The *Est_FG_Date* is calculated

based on the standard cycle time of each stage (routing).

7) *Est_FG_Qty*. The estimated finish good quantity, the expected quantity which the current material becomes the final finish goods. The *Est_FG_Qty* is calculated based on the expected *Yield* of each stage.

8) *Yield*. Determined as the ratio *Output Qty/Input Qty*.

The derived fields are only by way of example as any number of additional derived fields may be added as the need arises.

```

After the input data has been mapped and stored as raw data as described above and in connection with TABLE 2, TABLE 3, TABLE 4 and TABLE 5, the mapped raw input data is then processed in the DATA INTEGRITY UNIT 88-6 including the Data Checking unit 88-6₁ and the Data Cleansing 88-6₂ to improve the quality of the raw data.

One of the significant barriers to efficient supply chain management is poor data quality. A large amount of the data is provided by suppliers for Fabless semiconductor buyers. The buyers and suppliers (together clients of the supply chain management system) are connected in common over the Internet and the suppliers supply local supplier information to said system via electronic records and reports. A record is a single entry at one time and reports reflect accumulated data from a number of records or other reports. The data integrity unit of FIG. 11 operates to process the raw data to obtain clean processed data. The clean processed data is checked for consistency with buyer's original local information as well as the local information provided by all the other suppliers in the supply chain.

The data integrity processing is divided into five parts:

- Part 1. Data Consistency Within a Record.
- Part 2. Data Consistency Within a Report.
- Part 3. Data Consistency Across Different Reports from a Particular Supplier.
- Part 4. Data Consistency Between Supplier and Buyer Data.
- Part 5. Data Consistency Between Suppliers.

In connection with the different parts, the data relates to WIP (Work In Progress) Reports, activity-based Transaction Reports (TR) including Daily Transaction Reports (DTR), Orders including Purchase Orders (PO) and Work Orders (WO), Shipment Reports and Invoices.

For each of Part 1 to Part 5, cleansing is performed for Static Data Consistency and for Dynamic Data Consistency. By way of example, for Static Data Consistency, in a PO, the Lot No, and Part No are checked for consistency. By way of example, for Dynamic Data Consistency, Date Sequence, Quantity Sequence and Routing Sequence are checked.

In connection with Part 1, Data Consistency Within a Record, typically the following are checked:

1. Required Field Missing.
2. Date Sequence Check. For example, the sequence
 $ordered\ date \leq received\ date \leq start\ date$
 $\leq completed\ date \leq shipped\ date$ is
checked where " \leq " means "is earlier than".
3. Quantity Sequence Check. For example, the
sequence $received\ qty \geq start\ qty \geq$
 $completed\ qty \geq shipped\ qty$ is checked
where " \geq " means "is greater than or equal
to".
4. Date out of Reasonable Range. For example,
 $(current\ date - start\ date)$ is too large and
 $estimated\ completion\ date$ is before the
 $current\ date$.
5. Quantity out of Reasonable Range. For example,
 $scrap$ or $downgrade\ quantity$ too big.
6. Status of a Lot Inconsistent with WIP Quantity.
7. Data Dictionary Check. Key data is included and
cross-referenced. For example, $device$ is not
found in $device\ master\ table$, $item\ number$ is
not found in $item\ master\ table$, WIP status
key word is not conformed to the

pre-defined specification. A master dictionary for each type of data is stored in the master table to enable checking to be performed.

5

As an example in connection with Part 2, Data Consistency Within a Report, the following are checked:

1. Duplicated Data Check. For example, the same lot appears in more than one record in a WIP or the same transaction appears twice in a DTR.
2. Date Sequence Error. For example, *complete-out* before *receive-in* transaction in DTR.
3. Status Sequence Error. For example, status sequence should be: *(scheduled)<(active or hold)<(completed or closed) <(ship or closed)* where "<" means prior to.

10

15

As an example in connection with Part 3, Data Consistency Across Different Reports from a Particular Supplier, the following are checked:

20

1. Data Content Inconsistency. For example, *device* or *item* has no changes for the same lot at a different date.
2. Quantity Inconsistency. For example, *total quantity* (WIP + *scrap* + *warehouse*) changes for the same lot on a different date.
3. Date Inconsistency. For example, *start date* or *completion date* changes for the same lot.

25

- 5
4. WIP Movement Error. For example, a lot has been completed then moves back to WIP.
 5. Status Sequence Error. For example, a lot moves to *complete* before becomes *active*.
 6. Abnormally Long Cycle Time.
 7. Abnormally Low Yield.

As an example in connection with Part 4, Data Consistency Between Supplier and Buyer's Data, the following are checked:

- 10
1. Date Sequence Error. For example, a downstream supplier received before the upstream supplier shipped.
 2. WIP Movement Error. For example, the same lot appears at two different suppliers at the same time.
 3. Status Sequence Error
- 15
4. Abnormal Long Cycle Time
 5. Shipped but Not Received
 6. Shipped Quantity Does Not Equal Received Quantity

As an example in connection with Part 5, Data Consistency Between Suppliers, the following are checked:

1. Consistency Between Purchase Order and Work Order. For example, *device* and *item no* should be consistent; sum of *work order cost* should be equal or less than the *blanket purchase order* amount.
2. Consistency Between WIP and Production Order. For example, *Production Order No*, *Device*, *Item No*, and *Qty* in WIP should match with the production order information.
3. Consistent Between DTR and Production Order. For example, production order no, *device*, item no, and *qty* in DTR should match with the production order information.
4. Consistency Between WIP and DTR. For example, the difference in WIP between the two consecutive dates should be equal to amounts shown in DTR.
5. Consistency Between DTR and Shipment Report.
6. Consistency Between DTR and Inventory. For example, the Inventory report should be equal to the results obtained by the cumulative DTR.

FIG. 12 depicts one example of a multiple supplier branch in a supply chain transaction where after the Wafer Sort stage by supplier *testa*, the Assembly stage for a lot is distributed to three suppliers, namely *pkgk*, *pkgz* and *pkgftp*.

In FIG. 12, the Raw Material is an input to the Fab stage at supplier *fabc* and Lot No T0239A is assigned. When the Fab stage work is complete, a Wafer

Shipping Notice is issued and the wafers are delivered for the Wafer Sort stage to supplier *testa* for the Lot No T0239A. When the Wafer Sort stage work is complete, a Sorted Wafer Shipping Notice is issued and the scribed wafers are delivered for the Assembly stage to Assembly supplier *pkgk* with Lot No T0239A-1 assigned, are delivered for the Assembly and Final Test stages to Assembly & Final Test supplier *pkgz* and Lot No T0239A-2 is assigned, and delivered for the Assembly and Final Test stages to Assembly & Final Test supplier *pkgftp* and Lot No T0239A-3 is assigned. When the Assembly supplier *pkgk* with Lot No T0239A-1 completes the packaging, a Assembled Die Shipping Notice is issued and the packaged devices are delivered for the Final Test stage to the Final Test supplier *pkgftp* with Lot No T0239A-1 retained. When the Final Test supplier *pkgftp* finishes the Final Test on Lot No T0239A-1, the Finished Goods are available. When the Final Test supplier *pkgz* finishes the Final Test on Lot No T0239A-2, the Finished Goods are available. When the Final Test supplier *pkgftp* and finishes the Final Test on Lot No T0239A-3, the Finished Goods are available.

FIG. 13 depicts cross supplier error checking in the example of FIG. 12. The Wafer Sort stage supplier *testa* for the Lot No T0239A-2 has an Out Date, indicated by 2* in FIG. 13, of 2/28/2002 where the designated supplier is *pkgz*. The supplier *pkgz* for the Lot No T0239A-2, however, has an In Date, indicated by 2* in FIG. 13, of 1/28/2002 which of course is an error since the goods could not have been received by *pkgz* before they were shipped by *testa*. This error is detected by the DATA INTEGRITY UNIT 88-6 of FIG. 11.

In FIG. 13, the Assembly stage supplier *pkgk* for the Lot No T0239A-1 has a QTY/die Out quantity, indicated by 1* in FIG. 13, of 3200 where the designated supplier is *pkgftp*. The supplier *pkgftp* for the Lot No T0239A-1, however, has a QTY/die In quantity, indicated by 1* in FIG. 13, of 4200 which of course is an error since more goods could not have been received by *pkgftp* then were shipped by *pkgk*. This error is detected by the DATA INTEGRITY UNIT 88-6 of FIG. 11.

FIG. 14 depicts one example of a lot tracking report. Lot Tracking is executed by the BUSINESS LOGIC 98-2 of FIG. 10 to store detailed information related to a lot in the production supply chain. The information tracked in the lot tracking has two categorizes as follows:

5 **Category 1.** Static Data: where the data are fixed during
the manufacturing processes.

Category 2. Dynamic Data: where the data can be changed during the manufacturing processes.

10 The Static Data includes:

- | | | |
|----|----|----------------------|
| | a) | Lot number, |
| | b) | Part no, |
| | c) | Purchase order no, |
| | d) | Production order no, |
| 15 | e) | Date code, |
| | f) | Supplier, |
| | g) | Routing, |
| | h) | Order date, |
| | i) | Order Qty, |
| 20 | j) | Unit Price, |

The Dynamic Data includes two main parts, namely, Date Information and Qty Information where they have the following subparts :

- | | | | |
|----|--|----|--------------------------|
| 25 | | a) | Date Information: |
| | | | 1) Received date |
| | | | 2) Start date |
| | | | 3) Hold date |
| | | | 4) Completed date |
| | | | 5) Ship date |

b) Qty Information

- 1) Received Qty
- 2) Returned Qty
- 3) Start Qty
- 5 4) Hold Qty
- 5) Completed Qty
- 6) Good part Qty
- 7) Scrap part Qty
- 8) Downgrade Qty
- 10 9) Ship Qty

Lot tracking records the flow of a lot by keeping its genealogy in order to track the lot history. These records include a parent-child relationship for the unsplit lots and include a sibling relationship for split lots. Lot tracking information is loaded, for example, using WIP or DTR information. Lot tracking keeps a complete and consistent data set for all the production and finance related information in one central place, that is, in the 97-2 of FIG. 11. With this common repository of lot information for the entire supply chain, performance checking (such as cycle time and yield analysis) and detailed cost reports down to the lot details are provided supply chain management system.

In lot tracking and as shown in the FIG. 14, the supply chain management system assigns a Base Lot number to every lot. In FIG. 14, that Base Lot number is N1805 and a Lot No related to the Base Lot number is also kept so that the routing to and local identification for each of the suppliers is recorded in the lot tracking information. The particular Base Lot number N1805 of FIG. 14 has a ROUTE that traces the sequence Fab at supplier *fabk* with Base Lot number N1805, Wafer Sort at supplier *testa* with Base Lot number N1805, Assembly at supplier *pkgk* with Lot No N18058 and Final Test at supplier *pkgftp* with Lot No N18058.1, with Lot No N18058.2 and with Lot No N18058.3.

FIG. 15 depicts a first cross supplier lot tracking example. In FIG. 15, the Raw Material is an input to the Fab stage at supplier *fabc* and Lot No N1805 is assigned. When work at the Fab stage is complete, a Wafer Shipping Notice is issued and the wafers are delivered for the Wafer Sort supplier *testa* for the Lot No N1805. When the Wafer Sort stage work is complete, a Sorted Wafer Shipping Notice is issued and the sorted wafers are delivered for the Assembly stage to Assembly supplier *pkgk* with Lot No N1805S assigned. When the Assembly supplier *pkgk* with Lot No N1805S completes the packaging, an Assembled Die Shipping Notice is issued and the packaged devices are delivered for the Final Test stage to the Final Test supplier *pkgftp* with Lot No N1805S.1, Lot No N1805S.2 and Lot No N1805S.3 assigned. When the Final Test supplier *pkgftp* finishes the Final Test on Lot No N1805S.1, Lot No N1805S.2 and Lot No N1805S.3, the Finished Goods are available for each of those lots.

FIG. 16 depicts a second cross supplier lot tracking example. In FIG. 15, the Raw Material is an input to the Fab stage at supplier *fabc* and Lot No T0239A is assigned. When the Fab stage work is complete, a Wafer Shipping Notice is issued and the wafers are delivered for the Wafer Sort stage to supplier *testa* for the Lot No T0239A. When the Wafer Sort stage work is complete, a Sorted Wafer Shipping Notice is issued and the sorted wafers are split into three orders and are delivered for the Assembly stage to Assembly supplier *pkgk* with Lot No T0239A-1 assigned, are delivered for the Assembly stage to Assembly supplier *pkgz* with Lot No T0239A-2 assigned and are delivered for the Assembly stage to Assembly supplier *pkgftp* with Lot No T0239A-3 assigned. When the Assembly supplier *pkgk* with Lot No N1805S completes the packaging, a Assembled Die Shipping Notice is issued and the packaged devices are delivered for the Final Test stage to the Final Test supplier *pkgftp* with Lot No N1805S.1, Lot No N1805S.2 and Lot No N1805S.3 assigned. When the Final Test supplier *pkgftp* finishes the Final Test on Lot No N1805S.1, Lot No N1805S.2 and Lot No N1805S.3, the Finished Goods are available for each of those lots.

FIG. 17 depicts an Actual Cost - Lot Detail Report for the Lot No N18005S.1 from Final Test Supplier *pkgfip* of FIG. 15. The ability of the supply chain management system to run the FIG. 15 reports results from the Lot Tracking that is performed. In order to perform Lot Tracking, the mapping of fragmented information among multiple Suppliers is required. The accuracy of the report depends on the accuracy of the information and hence the data integrity processing is important to report accuracy.

FIG. 18 depicts the purchase order logic flow for creation and acceptance of orders. Such orders are of the type described in connection with FIG. 5, FIG. 6 and FIG. 7 where a buyer issues a set of dependent purchase orders in order to progress Raw Materials to Finished Product. As a first step, a Buyer will initiate the process Buyer Create BPO entry at A to create a blanket purchase order. The terms of the BPO are set and may be a standard contract with standard terms and conditions of the Buyer. Normally, the BPO undergoes one or manager approvals for the Buyer usually based upon price thresholds for each manager. The higher the price, the more management levels that may be required. No Manager1Approve ? is required if the price is less than a first threshold, $\text{Price} \leq \$T1$, and a Yes results sending the BPO to the Supplier input C. If the BPO price is not less than a first threshold, $\text{Price} \leq \$T1$, and a No results, a Manager1Approve ? is required and if a No results, a return is made for further adjustment of the BPO. If a Manager1Approve ? is required and is Yes, the approval process continues for one or more additional approvals. For example, when no Manager2Approve ? is required (the price is less than a second threshold, $\text{Price} \leq \$T2$) and a Yes results sending the BPO to the Supplier input C. If the BPO price is not less than a second threshold, $\text{Price} \leq \$T2$, and a No results, a Manager2Approve ? is required and if a No results, a return is made for further adjustment of the BPO. If a Manager2Approve ? is required and is Yes, the approval process continues for one or more additional approvals. Assuming Manager2Approve ? is the last required and a Yes results sending the BPO to the Supplier input C.

If a BPO exists, or in the absence of a BPO if one is not to be used, a Buyer from time to time will initiate the process Buyer Create PO entering at B to create a purchase order. The terms of the PO are set and may be a standard contract with standard terms and conditions under the BPO of the Buyer or otherwise. As a first
5 step, a Conditions OK? check is made to make sure that conditions are properly established for the PO. If the current PO is dependent upon the output of another stage, perhaps from a different Supplier, the conditions precedent for the PO are checked and if satisfied, a Yes will forward to a Terms OK? check and if not a No will return to PO for further processing. As a second step, a Terms OK? check is
10 made to make sure that terms of the PO are correct. For example, if the PO is under a BPO, then a check is typically made to determine if the quantity and cost is within the balance remaining on the BPO. If the terms for the PO are checked and if satisfied, a Yes will forward to a Terms Adjust where, for example, the amount of the current PO will decrement the balance remaining on the BPO. If the Terms
15 OK? check is not satisfactory, a No will return to PO for further processing. Normally, the PO undergoes one manager approval Manager0 Approve? and if a Yes results, the processing is sent to the Supplier input C and if No, process is sent to PO for further processing of the PO

When a Supplier receives a Supplier Accept BPO/PO input, entering at C
20 to create approval of a Buyer purchase order. The terms of the PO are set and may be a standard contract with standard terms and conditions under the BPO of the Buyer or otherwise. As a first step, a BPO Terms OK? check is made to make sure that terms are properly established for the PO or BPO. If the terms of the BPO are OK, a Yes will forward to a Terms OK? check and if not a No will return to
25 BPO/PO for further processing. As a second step, a PO Terms OK? check is made to make sure that the terms of the PO are correct and if Yes will forward processing for manager approval. If the Terms OK? check is not satisfactory, a No will return to BPO/PO for further processing. Normally, the PO undergoes one

manger approval Manager Approve? and if a Yes results, the processing terminates with Order Confirmed.

FIG. 19 depicts an example of Final Test Purchase Order. The PO of FIG. 19 is in an on-line form to Supplier *pkgfip* and includes in the lower right-hand corner a thumbnail image of an attachment that details certain aspects of the PO. The ability of the supply chain management system to run reports of the FIG. 19 type relies upon the Lot Tracking facility. In order to perform Lot Tracking, the supply chain management system maps fragmented information that inherently is fragmented among multiple Suppliers since there is no agreed upon standard in the industry. As described, the local information for each client (Buyers and Suppliers) is mapped with reference to a master table that constitutes a super set of all the local tables for each of the clients. The accuracy of each report depends on the accuracy of the mapped information and hence the data integrity processing is important in order to be able to have reporting accuracy among multiple Suppliers and among multiple Buyers and multiple Suppliers.

FIG. 20 depicts an example of the attachment that appears as a thumbnail image in the Final Test Purchase Order of FIG. 19.

FIG. 21 depicts an example of a Wafer Rolling Output Report. . The ability of the supply chain management system to run reports of the FIG. 21 type relies upon the Lot Tracking facility. In order to perform Lot Tracking, the supply chain management system maps fragmented information that inherently is fragmented among multiple Suppliers since there is no agreed upon standard in the industry. As described, the local information for each client (Buyers and Suppliers) is mapped with reference to a master table that constitutes a super set of all the local tables for each of the clients. The accuracy of each report depends on the accuracy of the mapped information and hence the data integrity processing is important in order to be able to have reporting accuracy among multiple Suppliers and among multiple Buyers and multiple Suppliers.

FIG. 22 depict an example a Finished Goods Rolling Output Report. . The ability of the supply chain management system to run reports of the FIG. 22 type relies upon the Lot Tracking facility. In order to perform Lot Tracking, the supply chain management system maps fragmented information that inherently is fragmented among multiple Suppliers since there is no agreed upon standard in the industry. As described, the local information for each client (Buyers and Suppliers) is mapped with reference to a master table that constitutes a super set of all the local tables for each of the clients. The accuracy of each report depends on the accuracy of the mapped information and hence the data integrity processing is important in order to be able to have reporting accuracy among multiple Suppliers and among multiple Buyers and multiple Suppliers.

FIG. 23 depicts an example a Work in Progress Inventory Report. The ability of the supply chain management system to run reports of the FIG. 23 type relies upon the Lot Tracking facility. In order to perform Lot Tracking, the supply chain management system maps fragmented information that inherently is fragmented among multiple Suppliers since there is no agreed upon standard in the industry. As described, the local information for each client (Buyers and Suppliers) is mapped with reference to a master table that constitutes a super set of all the local tables for each of the clients. The accuracy of each report depends on the accuracy of the mapped information and hence the data integrity processing is important in order to be able to have reporting accuracy among multiple Suppliers and among multiple Buyers and multiple Suppliers.

In the supply chain management system, an alert process is provided that extends across the multiple Suppliers environment and the multiple Buyers and multiple Suppliers environment. Typically, a Buyer having an integrated circuit (IC) design relies upon Production Engineers, Production Control Engineers or other Production Control (PC) personnel to find problems and exceptions that require action or correction during manufacture and procurement. Procurement from a manufacturing supply chain having multiple dependent suppliers, that is,

where the output from one Supplier is the input for other Suppliers, has increased complexity when compared with less interdependent supply chains. If a Buyer can only use the Finished Product to solve problems, the job is tedious and error prone. The alert function is robust and extends to all stages in the supply chain. The alert
5 function as one of the supply chain management functions greatly enhances problem identification and correction in the supply chain.

The supply chain management system performs alert processes based upon alert conditions for specific events/reports/process. The alert conditions are selected by clients. Alert reports are accessible to clients through onscreen
10 operations or through other i-commerce methods of communication. Typically, alert conditions are communicated daily (or more frequently if desired) from the supply chain management system to clients in the form of event generation and alert messages.

By way of an example for the alert functions, it is assumed for purposes of explanation that for a particular part (PROD), in the process of P, the standard
15 production cycle time is X days. The production control (PC) personnel, or production control (PC) agent if an automated computer system, of a client specifies that if the *real cycle time* is longer than the *standard cycle time* by Y days, the client is to be alerted. The supply chain management system implements
20 the algorithm as follows in TABLE 6:

TABLE 6	
5	Store info by PROD, P, X (static info) Store info by PC, Y (Client dependent) Periodically check the rule (for example, each time a production report enters the supply chain management system) as follows: If report has product PROD If report is for process P If reported <i>completion time - start time</i> > X Store this record into <i>Cycle > stdCycleTime</i> With <i>CycleTime = completion time - start time</i> With product = PROD With process = p When client (PC) accesses report, If client is PC List any existing records in <i>stdCycleTime</i> Where product = PROD AND process = p AND <i>CycleTime > Y</i> .
10	
15	
20	

25 The implementation of TABLE 6 is suitable for both standard reports and client preferences for improved performance.

Alerts are divided into categories:

- 1) Abnormal time lapse:
 - a. *Long Queue-in Time*: The *Queue-in Time* is the period from receiving material (*Received Date*) to the start of the production (*Start Date*). A *Long Queue-in Time* is when the *Queue-in Time* is longer than a specified period. Usually a *Long Queue-in Time* results from a constraint in production capacity or a delay in paper work.
- 30

b. *Long In-process Time*: The *In-process Time* is the amount of time in a production process, WIP, and a *Long In-process Time* is when the *In-process Time* is taking an abnormally long time.

5 A Buyer or other client may define a threshold for 'long cycle time' (per routing stage) and the supply chain management system reports any active WIP beyond the specified threshold as a *Long In-process Time*.

10 c. *Long On-hold Time*: The *On-hold Time* is time when a production process, WIP, is put on hold due to a quality issue, a machine setup problem, a buyer request or other reason. A Buyer or other client may define a threshold for 'long hold time' (per routing stage) and the supply chain management system reports any active WIP beyond the specified threshold as a *Long On-hold Time*.

15 d. *Long In-house Warehouse Time*: During and after the production process, WIP, the materials or finished goods are usually put in the supplier's warehouse for temporary storage. This storage is called *In-house Warehouse Time* (also Die/Wafer bank time). A *Long In-house Warehouse Time* is when the *In-house Warehouse Time* is too long. A Buyer or other client may define a threshold for 'long in-house warehouse time' and the supply chain management system reports any storage beyond the specified threshold as a *Long In-house Warehouse Time*.

20

25

5 e. *Long In-transit Time*: The *In-transit Time* is the time lapse between the shipping of one supplier to the receiving of the following supplier. In-transit goods and materials generally are the most difficult to track in a supply chain. A Buyer or other client may define a threshold for 'in-transit time' and the supply chain management system reports any storage beyond the specified threshold as a *Long In-transit Time*. The supply chain management keeps a log of how long it takes from shipping to receiving at each stage.

10 f. *Early Complete Notice* – An early warning (x-days before the estimated completion date) is provided to enable a PC to start planning the production flow. This feature is important for Fab and Wafer Sort stages.

15 g. *Stationary Lot Report* – A log to show lot movement during a given period.

20 2) Abnormal yield

a. *Low Yield Threshold* is defined by the Buyer or other client. The supply chain management system tracks yield down to per device, per part number, per supplier and identifies low yield.

25 b. *Excess Yield Threshold*. Sometimes, a supplier reports the output quantity larger than reasonable, such as greater than the input quantity causing a yield greater than 100%.

3) Order and invoice

5 a. *Missing PO.* When material is set aside for a manufacturing process, the accompanying PO has to be there for suppliers to start the work. However, this is not always done. The supply chain management system generates alerts for PC in these cases. The trigger can be set in any stage of the production flow: for example, when the upstream process is completed, or when the upstream production is shipped, or when the material is received.

10 b. *Cost Approval Delay.* When the production process is finished, the cost needs to be calculated and approved by PCs. If the cost calculation and approval process has too great a delay, it is difficult for PC to reconcile this info with the real production data, since it has been done a long time ago. The supply chain management system brings the cost calculation and approval process to alert the PC as soon as a particular process is done, it can reduce the future dispute and control the production cost.

20 c. *Cost Deviation.* If the unit cost of a particular unit is larger than a particular percentage of the standard cost for such unit, the supply chain management system will bring alert the PC, it can either be due to a low yield, or due to high unit cost.

25 d. *Received but PO Not Issued* – Lot received but PO has not been issued.

 e. *Shipped but PO for next Stage Not Issued* – Lot shipped but PO has not been issued for the following supplier.

- f. *Completed but PO Not Closed* – WIP status is completed and PO is not closed.
- g. *Completed but Invoice Not Approved* – WIP status is completed, invoice is received and waiting for approval.
- h. *Wip Quantity Larger than Ordered Quantity* – WIP quantity should be equal or less than order quantity, this check is particularly important for foundry PO/WIP reconciliation.
- 4) Performance Index (After the production is done):
- a. *Yield Report* – per device, part number, routing and supplier.
- b. *Cycle Time Report* – per device, part number, routing and supplier.
- 15 The supply chain management system employs planning based upon upstream visibility in the supply chain. Such capabilities are particularly useful in outsourcing to suppliers in a semiconductor supply chain. In the semiconductor IC-design outsourcing industry, the buyer (IC-design house) deals with multiple suppliers that provide various outsourcing functions at different supplier stages.
- 20 The buyer places a separate order (Purchase Order) with each supplier. Although the Purchase Orders are separate between a buyer and each supplier, each supplier depends on the previous supplier (upstream supplier) in the supply chain. In order to procure a chip as finished goods, a buyer first orders wafers from a Fab supplier (foundry); once the work at the Fab supplier is finished, the buyer orders sorting
- 25 from a Wafer Sort supplier; after the Wafer Sort work is finished, the buyer orders Assembly from an Assembly supplier; and finally, the buyer orders Final Test from a Final Test supplier. The supply chain management system, for example, is able to perform group order generation for groups of dependent suppliers (Fab, Wafer Sort, Assembly and Final Test suppliers) in the supply chain.

At each step of the supply chain, a downstream supplier waits for the previous upstream supplier to complete (or partially complete) its work before commencement of work under a new order can begin. The supply chain management system allows the buyer to create virtual downstream orders once upstream orders are underway. The supply chain management system uses estimated date (and continuously update as more up to date info is provided with the WIP data), to create virtual (future) orders for the downstream suppliers.

Besides providing the buyer with order creation, the supply chain management system also provides the suppliers with up to date information regarding up coming orders. Downstream suppliers can use the supply chain management system to view the current status of the materials, which will eventually be arriving and requiring their services.

In an example for describing the operation, a buyer has a requirement for final goods (FG) of amount Q chips on date D. Based upon this information, the supply chain management system operates as in the following TABLE 7:

TABLE 7

Calculate the initial wafer required:

Using Bill of Routing:

5

FG is made from FT-FG in Final Test with standard yield

Y_{ft} , standard cycle time D_{ft} , by supplier S_{ft} ,

Thus the date and quantity to start FT is:

$$Q_{-FT} = Q / Y_{ft}$$

$$FTD = D - D_{ft}$$

10

FT-FG is made from AS-FG in Assembly with standard
yield Y_{as} , standard cycle time D_{as} , by supplier S_{as} ,

Thus the date and quantity to start AS is:

$$Q_{-AS} = Q_{-FT} / Y_{as} = Q / Y_{ft} / Y_{as}$$

$$ASD = FTD - D_{as} = D - D_{ft} - D_{as}$$

15

AS-FG is made from WS-FG in Wafer Sort with standard
yield Y_{ws} , standard cycle time D_{ws} , by supplier
 S_{ws} ,

$$Q_{-WS} = Q_{-AS} / Y_{ws} = Q / Y_{ft} / Y_{as} / Y_{ws}$$

$$WSD = ASD - D_{ws} = D - D_{ft} - D_{as} - D_{ws}$$

20

WS-FG is made from FD-FG in Foundry, with wafer to die
ratio $W2D$, with standard cycle time D_{fd} , by
supplier S_{fd} ,

Thus the date and quantity to start FD is:

$$Q_{-FD} = Q_{-WS} / W2D = Q / Y_{ft} / Y_{as} / Y_{ws} / W2D$$

25

$$FDD = WSD - D_{fd} = D - D_{ft} - D_{as} - D_{ws} - D_{fd}$$

(for each lot there are 25 wafers)

$$QL_{-FD} = Q_{-FD} / 25$$

30 According to TABLE 6, the supply chain management system will generate
orders for each of the suppliers with the proper quantity and required date
(WS/AS/FT work orders are lot based).

Since the supply chain management system is connected to the supply chain management system Lot Tracking engine, which keeps track on all the WIP data, the supply chain management system will constantly update the Quantity and Date information in each of the subsequent orders.

5 Once those orders are generated, the buyer will be notified a few days (user specified) before the next order is needed to be submitted to the supplier. The user can then come to the supply chain management system and reconfirm the order and submit it. The entire process is automatic and accurate, and greatly increases the productivity of PC personnel of the IC-design company.

10 While the invention has been particularly shown and described with reference to preferred embodiments thereof it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the scope of the invention.

CLAIMS

1. (Original) A supply chain management system for clients where the clients include one or more buyers and a plurality of suppliers, where said one or more buyers place orders with ones of said suppliers for the processing of an input to an output through a plurality of supplier stages, said clients each using fragmented different local information particular to each of said clients, the improvement characterized by,
- 5 mapping means for mapping said local information for each of said clients to provide mapped raw data,
- data integrity means for executing data integrity processes on said raw data to improve the reliability of said raw data,
- 10 processing means for processing said raw data to provide processed data,
- a database store for storing the raw data and the processed data as master information,
- 15 logic means accessing the master information for executing supply chain management functions for said clients.

2. (Original) A supply chain management system for clients where the clients include a plurality of buyers and a plurality of suppliers, where said buyers place orders with a plurality of suppliers for the processing of an input to an output through a plurality of supplier stages, said clients each using fragmented different local information particular to each of said clients, the improvement characterized by,

5 network communication means for interconnecting said clients for maintaining said local information current in said supply chain management system,

10 a database store for storing master information in one or more tables having master information correlated to local information,

 global processing means for processing supply chain management information for all of said clients including,

15 correlation means for correlating said local information among said clients, said correlation means including,

 input mapping means for mapping said local information for each of said clients to provide mapped data for storage in said database store,

20 data integrity means for executing data integrity processes on said mapped data to provide corrected mapped data,

25 processing means for processing said corrected mapped data

to provide processed data for storage with said corrected mapped data in said data base store as master information,

logic means for accessing the master information
for executing supply chain management
functions for said clients to provide
management data,

output mapping means for mapping said management data into local data for said clients.

3. (Original) The system as in either one of Claims 1 and Claims 2 including means for connecting with clients through the Internet.

4. (Original) The system as in either one of Claims 1 and 2 including tables storing correlations between said master information and said local information for each of said clients.

5. (Original) The system as in either one of Claims 1 and 2 wherein said data integrity means includes data checking means for detecting errors in said mapped data.

6. (Original) The system as in either one of Claims 1 and 2 wherein said data integrity means includes data cleansing means for correcting errors in said mapped data.

7. (Original) The system as in either one of Claims 1 and 2 wherein said input is a lot.

5

8. (Original) The system as in either one of Claims 1 and 2 wherein said input is a lot and said lot is split at any one of said stages to two or more different stages performing the same type of processing.

10

9. (Original) The system as in either one of Claims 1 and 2 wherein said input is lots and wherein said lots, at any two or more of said stages performing the same type of processing, are combined for processing in a downstream stage.

15

10. (Original) The system as in either one of Claims 1 and 2 wherein suppliers supply local supplier information via electronic records.

20

11. (Original) The system as in either one of Claims 1 and 2 wherein suppliers supply local supplier information to said system via data in electronic records and reports and wherein said data integrity means operates to check for data consistency within records, data consistency within reports, data consistency across different reports from a particular supplier, data consistency among data from multiple suppliers and one or more buyers, data consistency among data from multiple suppliers.

25

12. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said supplier stages include one or more of Fab, Wafer Sort, Assembly and Final Test for processing from the input to the output.

13. (Original) The system of Claim 12 wherein said supplier stages include Fab, Wafer Sort, Assembly and Final Test and one or more additional stages.

5 14. (Original) The system of Claim 13 wherein said one or more additional stages include one or more of Packaging, Bumping and Marking.

15. (Original) The system of Claim 12 wherein said input is a lot.

10 16. (Original) The system of Claim 12 wherein said input is a wafer lot.

17. (Original) The system of Claim 12 wherein said input is a die lot.

15 18. (Original) The system of Claim 12 wherein said output is finished goods.

19. (Original) The system of Claim 12 wherein said output is dies.

20 20. (Original) The system as in either one of Claims 1 and 2 wherein said input includes a plurality of lots, wherein said database stores one or more tables for correlations between said master information and said local information for each of said buyers and suppliers for each of said lots and wherein each of said tables has unique base lots common to all tables for identifying said lots.

25

21. (Original) The system as in either one of Claims 1 and 2 wherein said input includes a plurality of lots, wherein said database stores one or more tables for correlations between said master information and said local

5 information for each of said buyers and suppliers for each of said lots and wherein each of said tables has unique base lots common to all tables for identifying said lots and wherein each of said stages has an additional lot number for each base lot whereby the combination of said base lot and the lot number represents the genealogy of said lots in said stages.

10 22. (Original) The system as in either one of Claims 1 and 2 wherein said input is a lot, wherein said database stores one or more tables for correlations between said master information and said local information for each of said buyers and suppliers and wherein each of said tables has a base lot common to all tables for identifying said lot.

15 23. (Original) The system of Claim 22 wherein said local information is RosettaNet information.

24. (Original) The system of Claim 22 wherein said clients are in the semiconductor manufacturing industry and said supplier stages for each lot include one or more of Fab, Wafer Sort, Assembly and Final Test.

20 25. (Original) The system of Claim 22 wherein said supplier stages for one or more of said lots is split among multiple Fab stages.

25 26. (Original) The system of Claim 22 wherein said supplier stages for one or more of said wafer lots is split among multiple Wafer Sort stages.

27. (Original) The system of Claim 22 wherein said supplier stages for one or more of said wafer lots are split among multiple Assembly stages.

28. (Original) The system of Claim 22 wherein said supplier stages for one or more of said wafer lots is split among multiple Final Test stages.
- 5 29. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and wherein said supply chain management functions provide a lot tracking report based upon said lot data.
- 10 30. (Original) The system of Claim 29 wherein said lot data is static data.
31. (Original) The system of Claim 30 wherein said static data includes Date Code, Lot No, Order Date, Order Qty, PO No, Routing, Sup, and Unit Price.
- 15 32. (Original) The system of Claim 29 wherein said lot data is dynamic data.
33. (Original) The system of Claim 32 wherein said dynamic data includes Date Information and Quantity Information.
- 20 34. (Original) The system of Claim 33 wherein said Date Information includes Completed Date, Hold Date, Received Date, Ship Date and Start Date.
- 25 35. (Original) The system of Claim 33 wherein said Quantity Information includes and Completed Qty, Hold Qty, Received Qty, Ship Qty and Start Qty.

36. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and said output is a chip product and wherein said supply chain management functions include an actual cost lot detail report.

5

37. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and said output is a chip product and wherein said supply chain management functions include a wafer rolling output report.

10

38. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and said output is a chip product and wherein said supply chain management functions include a finished goods rolling output report.

15

39. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and said output is a chip product and wherein said supply chain management functions include a work in progress inventory report.

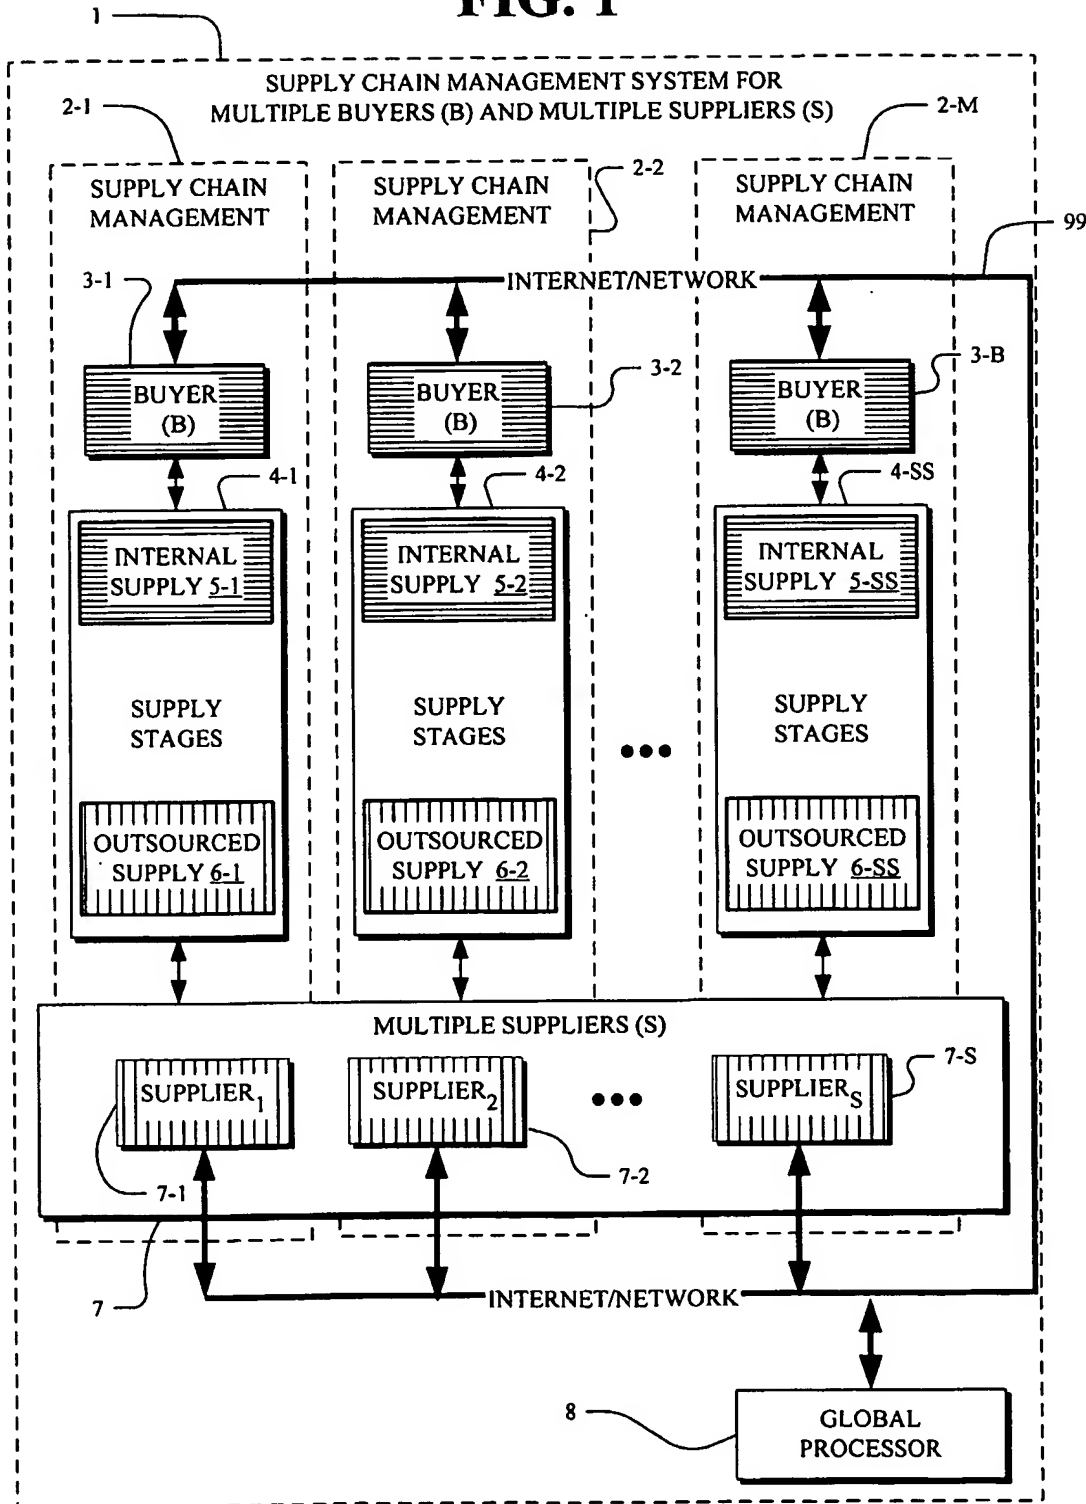

20

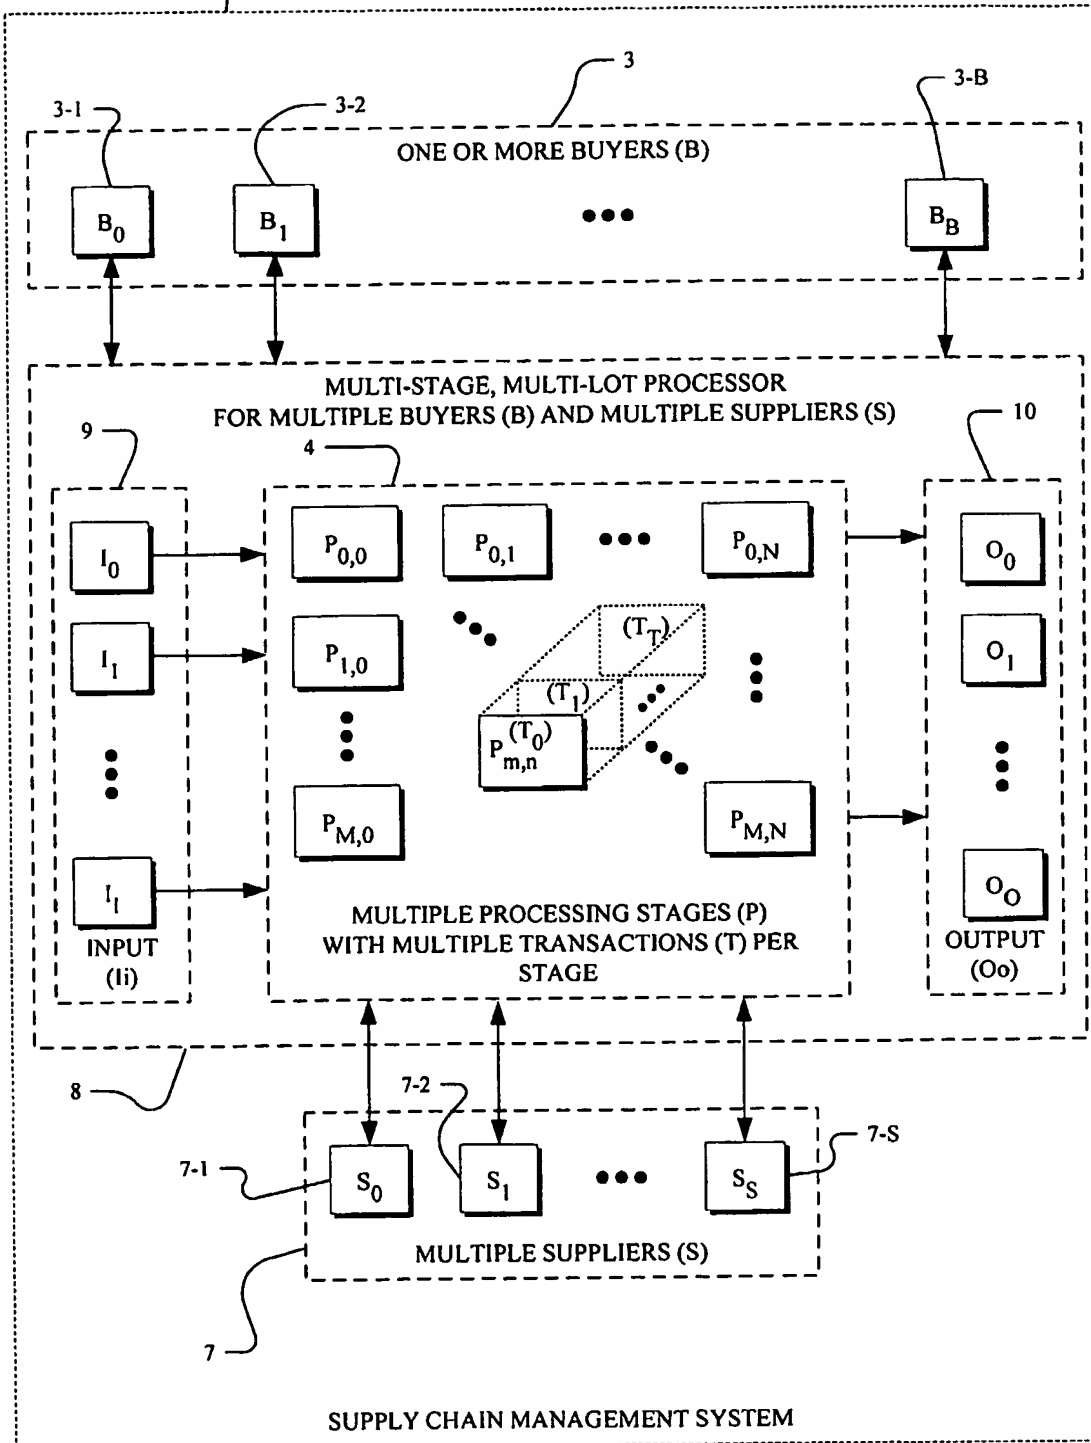

40. (Original) The system as in either one of Claims 1 and 2 wherein said clients are in the semiconductor manufacturing industry and said input is a wafer lot and said output is a chip product and wherein said supply chain management system functions to include an alert to signal a condition in the supply chain management system.

25

41. (Original) The system as in either one of Claims 1 and 2 wherein,
 said buyers, B, include buyers $B_0, B_1, \dots, B_b, \dots, B_B$,
 said suppliers, S, include suppliers $S_0, S_1, \dots, S_s, \dots, S_S$,
 said stages, P, include stages $[P_{0,0}, P_{0,1}, \dots, P_{0,N}]; [P_{1,0}, \dots]; [\dots, P_{m,n},$
 5 $\dots]; [P_{M,0}, \dots, P_{M,N}]$.
42. (Original) The system of Claim 41 wherein each of said stages, P,
 includes up to T transactions, T_0, T_1, \dots, T_T .
- 10 43. (Original) The system of Claim 42 wherein said T transactions are
 ORDER, WIP, YIELD, SHIPMENT, RECEIVE, WAREHOUSE and
 PAYMENT.
- 15 44. (Original) A method of supply chain management for clients where
 the clients include one or more buyers and a plurality of suppliers, where
 said one or more buyers place orders with ones of said suppliers for the
 processing of an input to an output through a plurality of supplier stages,
 said clients each using fragmented different local information particular to
 each of said clients, the improvement characterized by,
 20 mapping said local information for each of said clients to provide
 mapped data,
 executing data integrity processes on said mapped data to improve
 the reliability of said mapped data,
 processing said mapped data to provide processed data,
 25 storing the mapped data and the processed data as master
 information,
 accessing the master information to execute supply chain
 management functions for said clients.
